U-LITE: a proposal for scientific computing at LNGS

S. Parlati, P. Spinnato, S. Stalio LNGS 13 Sep. 2011

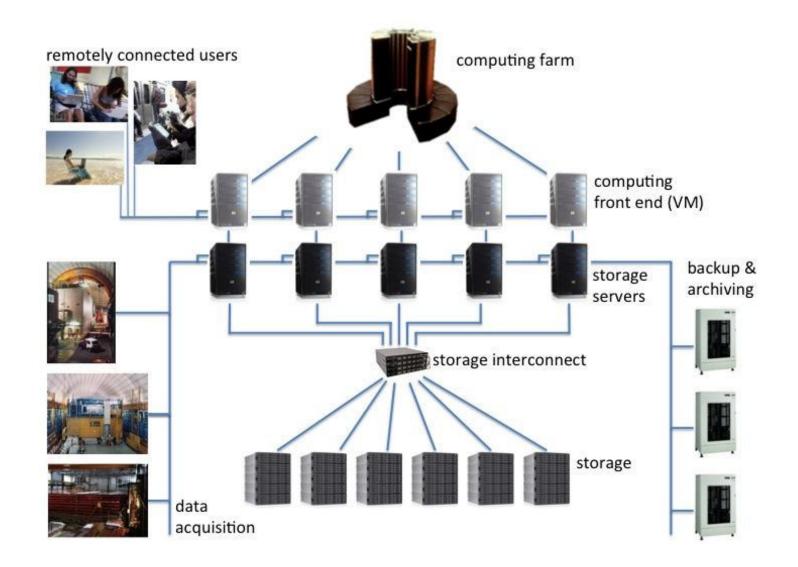

20 years of Scientific Computing at LNGS

- Early '90s: highly centralized structure based on VMS cluster and DECNET network.
- Late '90s 2000s: different unix systems (Digital Unix, Linuxes..); heterogeneous computing environments among collaborations. CNS continued to offer a complete computational environment (interactive, batch, storage, backup) even though various collaborations preferred to have their own farm.
 - 2008: first investigation on feasibility of a common infrastructure requested by INFN;
- 2010-2011:shared model, centrally managed; new techniques (virtualization) allow setup of heterogeneous environments on the same shared hardware -> U-LITE: right time to offer this service to future experiments!

Why do we want to do it?

- Offer a better service to the Experiments: create a complete computing environment in the place where it is most needed: where the data is actually collected. (Our size is typically much smaller than CERN LHC experiments and there is no need of unlimited resources).
- Ecomonic: resource sharing reduces expenses for infrastructure and optimizes resource exploitation
- Human resources: central management by on-site experienced personnel will allow experiments to save on human resources and avoid problems caused by unqualified or unmotivated personnel.

Overview

The U-LITE ingredients

- Storage servers: 1 or 2 for each experiment. They will copy data from DAQ to storage system, run first analysis or data reduction, save data to backup systems and present data to login servers and to the computing farm.
- Computing front-end: 1 or more per each experiment. They are accessed by users for sw development, for interactive tasks and to submit jobs to the computing cluster.
- Computing farm: many VM for each experiment, hosted inside real server (VM container). They will run batch jobs.
- Authentication and Authorization: users are managed centrally through Kerberos and LDAP databases.

Why experiments should join U-LITE?

- Less work for the experiments to setup a computational environment
- Freedom for the experiments to develop software for simulations and analysis on almost every linux dialect and with any kind of library and tool
- No need to adapt to GRID environment
- Stable and continuous presence of skilled staff on-site for infrastructure management
- Savings guaranteed by resource sharing
- Central monitoring of all the IT components

Why can we do it?

- The CNS staff at LNGS has a valuable experience in managing all the U-LITE subsystems: it manages the network infrastructure and all the basic network services, multiple storage systems for a total of 150TB, two tape libraries, NFS and AFS servers, interactive login servers, LSF batch jobs system and centralized Authentication and Authorization systems.
- All the subsystems operate in high availability mode and are checked by a central monitoring system.
- The CNS has a long experience working with host virtualization (used for network services high availability).

Funding

In the shared model we propose, funding should come from:

Experiments
Laboratory through the CNS
INFN National Computing committee.

The way the three players will contribute has not yet been finalized and discussions with the INFN scientific and computing committee are necessary in the near future.

Who is involved?

Responsibilities

- Management and coordination: S. Parlati
- Technical and operational responsibilities: P. Spinnato and S. Stalio
- Supervision and planning: G. Di Carlo

Technical staff

- O Basic services: all the CNS
- O Dedicated staff: P. Spinnato and S. Stalio
- OHuman resources requirements:
 - 3 FTE, distributed among the existing staff and trainees, for the setup of the U-LITE project
 - 1.5 FTE distributed between two or more members of the CNS staff when U-LITE will be up and running

Current status and future work

- All the U-LITE HW and SW components are tested and ready: a first production environment has been operating since April 2011.
- HW rearrangement will be done in Sep/Oct.
- Storage and backup are consolidated; computing environment is young and under continuous development.
- The whole system is scalable
- The HW pool will increase as new experiments join U-LITE.

Data Center

- All U-LITE subsystems live in the LNGS computing centre.
- The LNGS computing centre includes the main computer room and a second, smaller room in a different building.
- As for U-LITE, all systems are installed in the main computer room except for one of the two backup systems (server + tape library).

Computer Room Characteristics

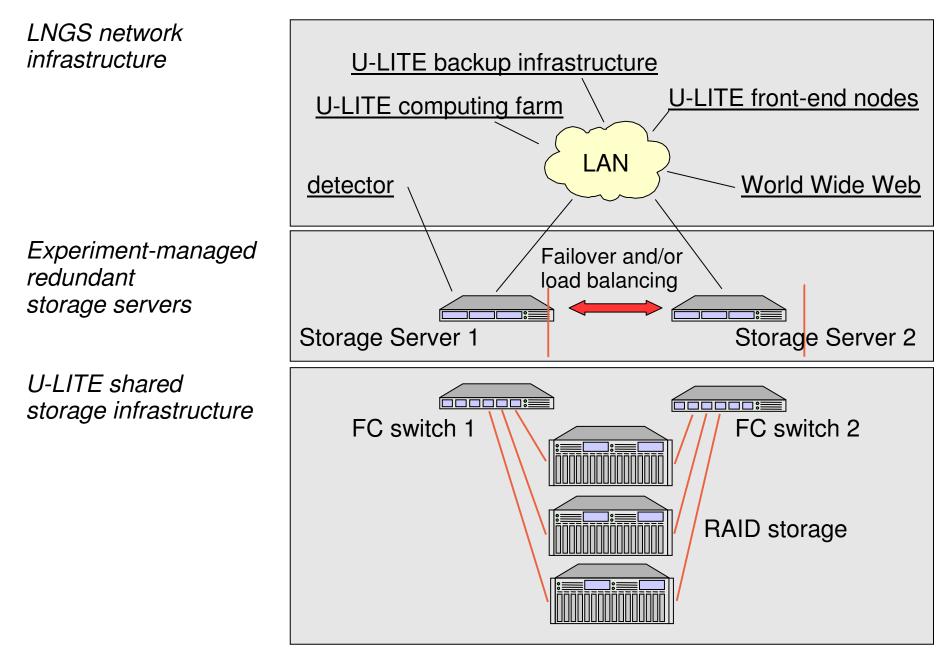

Reliable power distribution infrastructure:

Diesel generator activates in case of black-out
 3 UPS in parallel cover short power outages
 Redundant power distribution lines (2012)

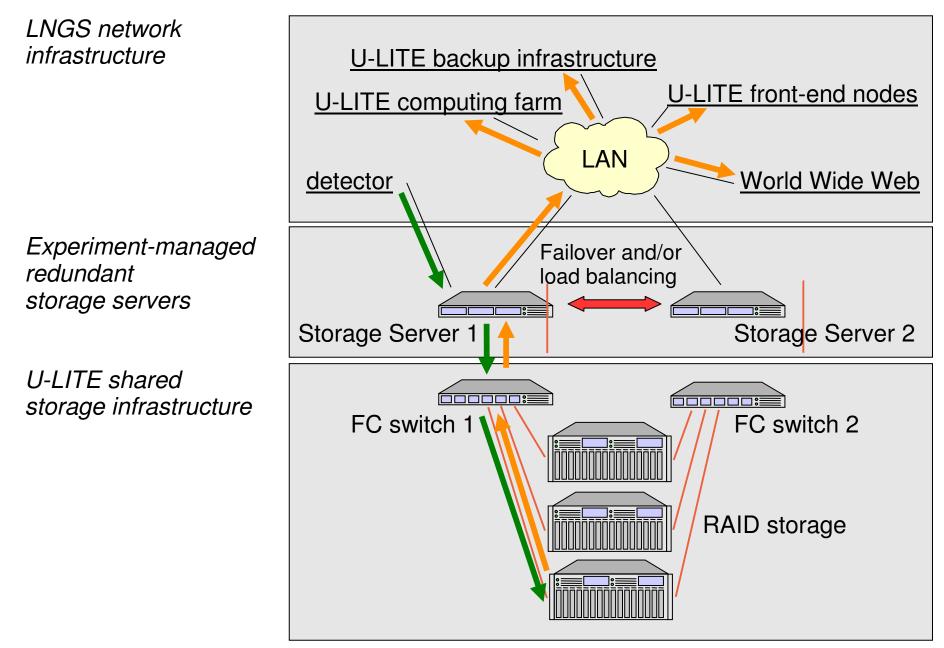

- Multiple, independent, cooling systems. Failure of one system is not an issue for normal operativity.
- Computer room is large and near offices. Operator intervention is thus quick and easy.

Storage

- Experimental data is copied from the detector DAQ to the U-LITE storage infrastructure via the LNGS LAN or a dedicated connection.
- Data is kept on reliable storage systems with redundant components (RAID, FC/iSCSI controllers, power supplies).
- Each experiment should have two storage servers connecting to the storage systems via different FC (or iSCSI) channels.
- Storage servers are managed by experimental collaborations. The LNGS CNS gives advice and guidelines.

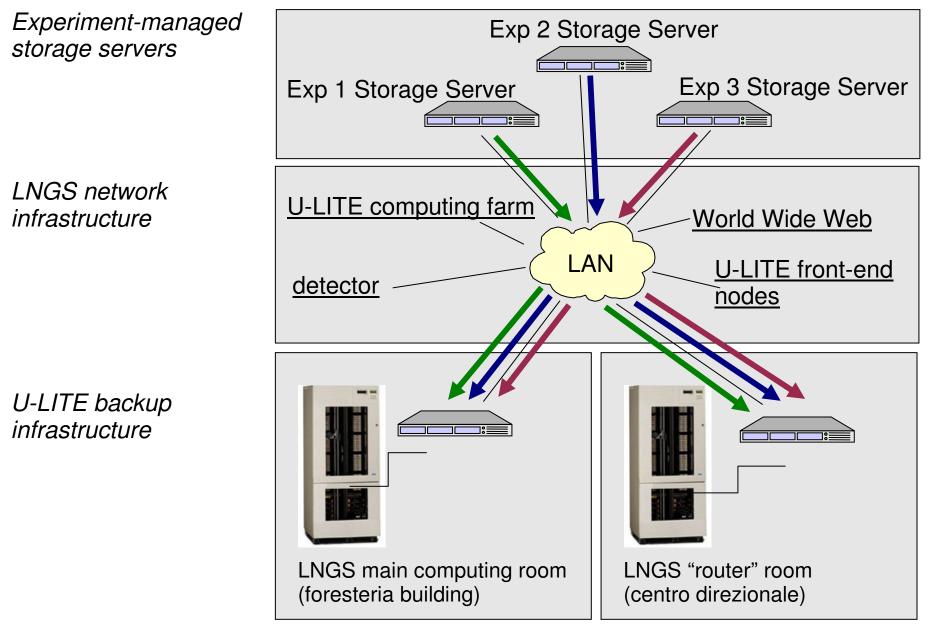

S. Parlati, S. Stalio, P. Spinnato – LNGS 13 Sept, 2011

S. Parlati, S. Stalio, P. Spinnato – LNGS 13 Sept, 2011

Backup and Archiving

- Experimental data is backed-up on two separate tape libraries, located in separate buildings. Each data set is backed-up on both libraries.
- An open-source software (bacula) is used for data backup. As the data format is open, long term data readability is ensured. Data can be easily read on standalone systems outside LNGS.
- No periodic full backups are performed. Extremely large data sets (>10TB) may not be kept on-line inside the tape library.
- Long term data archiving in a dedicated room is available.
- Data backup and archiving is managed by the LNGS CNS.
 Storage policies may have to be agreed upon with experiments.

S. Parlati, S. Stalio, P. Spinnato – LNGS 13 Sept, 2011

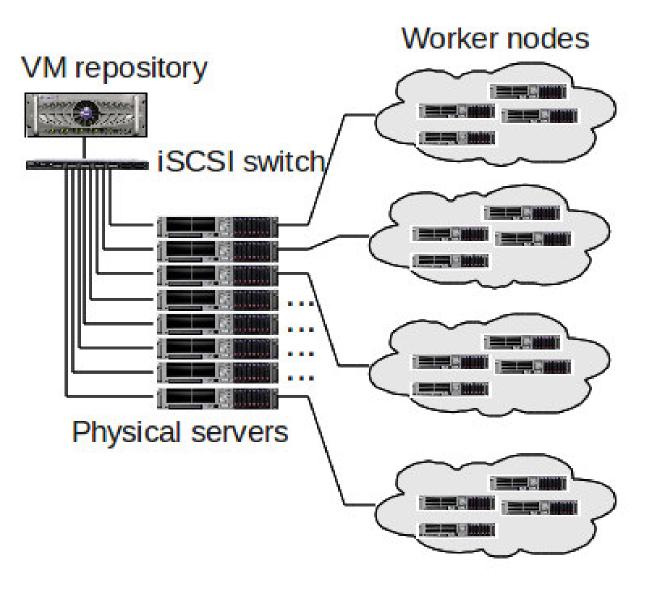

Computing Cluster

- The U-LITE computing cluster is based on (KVM) virtual hosts as computing nodes. U-LITE computing nodes are hosted inside a cluster of physical multicore servers managed with the open source "Proxmox VE" software.
- Each experiment/workgroup has its own computing nodes based on a custom template.
- Computing nodes are automatically instantiated, migrated or turned off according to resource requests.

Computing Cluster

 Computing node images are kept on a storage system that the physical servers share.

 Each computing node can always be <u>started on</u> or <u>migrated to</u> any server with no need to physically copy disk images.

S. Parlati, S. Stalio, P. Spinnato – LNGS 13 Sept, 2011

Monitoring

- Each component of the U-LITE system is continuously monitored for failures and overload.
- Mail/SMS messages are sent to CNS and/or to collaboration staff in case of problems.
- Historical data can be used for system tuning and for the discovery of weaknesses and bottlenecks.

The U-LITE computing infrastructure

- Hardware made up of multicore servers, which act as containers of Virtual Machines
- Computing nodes are Virtual Machines, managed by a common user-transparent virtualisation system
- Job submission through front-end nodes using the open source TORQUE-Maui software
- Hardware financed by collaborations according to their needs, plus extra resources provided by CNS
- Priority allocation within reasonable time of financed resources enforced by a specifically designed allocation algorithm

Why Virtual Machines

- Optimal exploitation of modern computing hardware calls for Virtual Machines
- By using VMs, collaborations are free to build their own computing environment, while using a common infrastructure
- CPU overhead is negligible, network and disk access overhead are acceptable

Computing node build-up

- VM templates are developed by collaborations, CNS offers advice and support, validates template, makes computing node clones. Basic templates are also available.
- Front-end nodes (which may be template clones themselves) are used for software development, running interactive jobs, submitting batch jobs
- Authentication and Authorization are based on the LNGS AA infrastructure

Batch job submission

User connects to collaboration front-end node

User submits job on the most appropriate queue using TORQUE-Maui

PAN algorithm decides job priority

CRM wakes up VMs according to PAN scheduling

TORQUE-Maui allocates jobs to VMs

→ High availability of front-end nodes and TORQUE-Maui server is guaranteed by stand-by backup nodes

S. Parlati, S. Stalio, P. Spinnato – LNGS 13 Sept, 2011

Resource allocation in U-LITE

Resource allocation must:

- guarantee for each collaboration fast access to resources which it has paid for
- maximise exploitation of available resources
- distribute homogeneously free resources to all collaborations needing them
- We have developed a *Privileged Allocation of computing Nodes* (PAN) algorithm to fulfill such requirements

The PAN Algorithm

2 pools:

• Priority pool for collabs that have not exhausted its resource quota

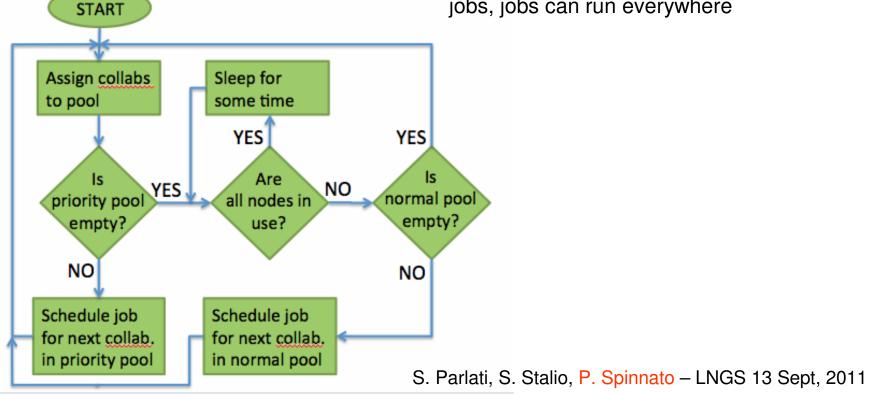

• Normal pool for collabs that have exhausted its resource quota and need extra resources

3 queues:

• Long queue for unlimited duration jobs, jobs can only run on collab. resource quota

• Short queue for limited duration jobs, job can run everywhere

• Express queue for very urgent and short jobs, jobs can run everywhere

Resource allocation

future developments

- Hot migration to slow nodes in case Privileged Allocation requires it
 - → VM disk space resident in a common Storage Area makes this straightforward
 - → Queue model changes accordingly: from duration-based to allocation-based
- VM hibernation in case all resources are occupied
- VMs used also to run interactive jobs
- Hardware configurable at job submission
- Resource allocation mechanisms highly configurable and open to replacements

S. Parlati, S. Stalio, P. Spinnato – LNGS 13 Sept, 2011

Job execution

- Process runs on VM computing node, username is the one who submitted job on front-end node
- Input data accessed via network
- After job completion, VM stays up in case other jobs requiring it arrive, or switches off, if needed, to free resources.

Job monitoring

S. Parlati, S. Stalio, P. Spinnato – LNGS 13 Sept, 2011

☆ 🌂

[🔇] U-Lite computing cluster on 🙁 🕀

U-LITE vs Grid/Cloud

Pros

- System managers are in direct contact with users (in contrast to Cloud)
- Extremely user-friendly: IT infrastructure is transparent to user (in contrast to Grid)
- Data and computing are co-located (in contrast to both)

Cons

- (little) risk of resource saturation
- Maybe more costs for hardware
